Absolutely continuous invariant measures

Stability of acim

Piecewise expanding maps of interval

ABSTRACT

For families of piecewise expanding maps which converge to a map with a fixed or periodic turning point touching a branch with slope of modulus equal to or less than 2, the standard Lasota–Yorke argument fails to prove stability. It is the goal of this paper to use instead the harmonic average of slopes condition for a large class of maps satisfying the summable oscillation condition for the reciprocal of the derivative. Using Rychlik's Theorem for a family of perturbations we prove weak compactness in L^1 of the density functions associated with them. From this it follows that we have stability of absolutely continuous invariant measures of the limit map.

1. Introduction

The main motivation for this investigation is to prove stability of the absolutely continuous invariant measure (acim) for some maps with fixed or periodic turning points. The difficulty caused by periodic turning points was first noticed by Keller [1] who introduced the so called W -maps to display a wide range of limiting behaviour. We will study classes of maps more general than the W -maps.

For almost forty years the Lasota–Yorke inequality [2,3] has played a crucial role in establishing existence of absolutely continuous invariant measures and in studying properties of these measures. More precisely, in the setting where we have a single piecewise expanding map $\tau : I \rightarrow I$, the Lasota–Yorke method requires that we use an iterate τ^n for which we have $\inf |(\tau^n)'| > 2$. Then, the partition $\mathcal{P}^{(n)}$ of τ^n is used in an argument where the magnitude of the minimum length of $\mathcal{P}^{(n)}$ appears in the denominator of a term. This works if we are dealing with a single map or with a family of maps for which the n th iterate of all members of the family has slopes uniformly bounded away from 2 in modulus. Stability of acim in this situation was considered in [1,4]. However, in some important situations this does not happen. Consider, for example, Keller's W maps [1], where the limit map has $|\text{slope}| = 2$ at a turning fixed point $1/2$. In this situation the standard Lasota–Yorke inequality cannot be applied to a family of approximating maps since taking an iterate of these maps creates partition elements which go to 0 length. The papers [5,6] show instability of acim for this map. In the paper [7] stability of a more general W shaped map has been considered. The results of this paper inspired the introduction of the harmonic average of slopes condition.

Recently, the Lasota–Yorke inequality has been strengthened [8] by using the harmonic average of the slopes on each side of the partition points rather than the doubled reciprocal of the minimal slope. This allows us to show stability of the acim of the limit map for a larger class of maps. The smoothness assumption in [8] is piecewise C^{1+1} .

In this note, we generalize the use of the harmonic average of slopes condition to maps with much weaker smoothness properties, namely we assume only the summable oscillation condition for the reciprocal of the derivative. Unlike [8], we do not use the bounded variation technique. Our main tool is Rychlik's Theorem (see, e.g., [3]). We show that the invariant densities of families of perturbed maps form a uniformly bounded set in L^∞ which implies that it is weakly compact in L^1 . From this compactness property it follows that we have stability of the acim associated with the limit map.

In Section 2, we will define the class of maps we will consider and introduce the harmonic average slope condition. Then, we will recall Rychlik's Theorem [3, Theorem 6.2.1]. In Section 3, we rewrite Rychlik's proof and show that the harmonic average condition is enough for the result to hold. In Section 4, we prove the main result of this paper, which establishes weak compactness in L^1 of the densities associated with the perturbing family of maps. This in turn proves stability of acim of the limit map. This result stays true in many situations not covered by previous works. Examples are presented in Section 5.

2. Notation and preliminary results

Let $I = [0, 1]$ and let m be Lebesgue measure on I . We present the usual definition of a piecewise expanding map.

Definition 1. Suppose there exists a partition $\mathcal{P} = \{I_i := [a_{i-1}, a_i], i = 1, \dots, q\}$ of I such that $\tau : I \rightarrow I$ satisfies the following conditions:

- (1) τ is monotonic on each interval I_i ;
- (2) $\tau_i := \tau|_{I_i}$ is C^1 and $\lim_{x \rightarrow a_{i-1}^+} \tau'(x)$, $\lim_{x \rightarrow a_i^-} \tau'(x)$ exist; Let $M = \max_{x \in I} |\tau'(x)|$;
- (3) $|\tau'_i(x)| \geq s_i > 1$ for any i and for all $x \in (a_{i-1}, a_i)$.

Then, we say $\tau \in \mathcal{T}(I)$, the class of piecewise expanding transformations.

Let

$$s := \min_{1 \leq i \leq q} s_i. \quad (1)$$

Suppose $\tau \in \mathcal{T}(I)$ satisfies the following condition.

$$s_H = \max_{i=1, \dots, q-1} \left\{ \frac{1}{s_i} + \frac{1}{s_{i+1}} \right\} < 1. \quad (2)$$

The number $H(a, b) = \frac{2}{\frac{1}{a} + \frac{1}{b}}$ is called the harmonic average of a and b . Condition $H(a, b) > 2$ is equivalent to condition $\frac{1}{a} + \frac{1}{b} < 1$. If τ satisfies $s_H < 1$ we say that τ satisfies the harmonic average condition. Let

$$\delta := \min_{2 \leq i \leq q-1} m(I_i). \quad (3)$$

Note that to calculate δ we do not use the first and last subintervals of the partition.

Let

$$g_n = \frac{1}{|(\tau^n)'|},$$

wherever $(\tau^n)'$ is defined. Let $\mathcal{P}^{(n)} = \bigvee_{i=0}^{n-1} \tau^{-i}(\mathcal{P})$. Note that $\mathcal{P} = \mathcal{P}^{(1)}$. For any measurable subset A of $[a, b]$, let

$$\mathcal{P}(A) = \{J \in \mathcal{P} : \lambda(J \cap A) > 0\}.$$

Let $\gamma_n = \sum_{J \in \mathcal{P}^{(n)}} \sup_J g_n$.

For $J \in \mathcal{P}^{(n)}$, we define $\text{osc}_J \frac{1}{|\tau'|} = \max_J \frac{1}{|\tau'|} - \min_J \frac{1}{|\tau'|}$ and

$$d_n = \max_{J \in \mathcal{P}^{(n)}} \text{osc}_J \frac{1}{|\tau'|}.$$

Definition 2. We say that a map $\tau \in \mathcal{T}(I)$ satisfies the summable oscillation condition, or $\tau \in \mathcal{T}_\Sigma(I)$, if

$$\sum_{n \geq 1} d_n \leq D < +\infty.$$

Note that usually the summable oscillation condition means a similar condition for $|\tau'|$ and not $\frac{1}{|\tau'|}$ as here.

This condition is satisfied for example for the following maps:

- (i) piecewise in $C^{1+\varepsilon}$, i.e., with bounded derivative satisfying a Hölder condition;
- (ii) piecewise satisfying Collet's condition [9], i.e, the modulus of continuity of τ' satisfies

$$\omega(t) \leq \frac{K}{(1 + \log |t|)^{1+\gamma}},$$

as $t \rightarrow 0$, for some $K, \gamma > 0$ ($\gamma = 0$ is not enough);

- (iii) satisfying Schmitt's condition [10,11], i.e, summable oscillation condition for $|\tau'|$.

3. Main result

We now recall Rychlik's Theorem. The proof can be found in [12] or [3, Theorem 6.2.1].

Theorem 1. Let τ be a piecewise monotonic transformation of an interval $[a, b]$ satisfying the following three conditions.

(1) There exists $d > 0$ such that for any $n \geq 1$ and any $J \in \mathcal{P}^{(n)}$,

$$\sup_J g_n \leq d \cdot \inf_J g_n.$$

(2) There exist $\varepsilon > 0$ and $r \in (0, 1)$ such that for any $n \geq 1$ and any $J \in \mathcal{P}^{(n)}$,

$$m(\tau^n(J)) < \varepsilon \Rightarrow \sum_{J' \in \mathcal{P}(\tau^n(J))} \sup_{J'} g \leq r.$$

(3) $\gamma_1 = \sum_{J \in \mathcal{P}} \sup_J g < +\infty$.

Then τ admits an absolutely continuous invariant measure. Moreover, if f is a τ -invariant density then

$$\|f\|_\infty \leq \gamma_1 \frac{d}{\varepsilon(1-r)}. \quad (4)$$

Theorem 2. If $\tau \in \mathcal{T}_\Sigma$ and satisfies the harmonic average of slopes condition $s_H < 1$, then it satisfies the assumptions of Rychlik's Theorem.

Proof. Condition (1): note that $\sup g \leq \frac{1}{s}$. Let $J \in \mathcal{P}^{(n)}$, $x, y \in J$. We have

$$\frac{g_n(x)}{g_n(y)} = \frac{g(\tau^{n-1}(x))g(\tau^{n-2}(x)) \cdots g(\tau(x))g(x)}{g(\tau^{n-1}(y))g(\tau^{n-2}(y)) \cdots g(\tau(y))g(y)}.$$

For any $k = 0, \dots, n-1$, $\tau^k(x)$ and $\tau^k(y)$ belong to the same element J_k of $\mathcal{P}^{(n-k)}$. Using the inequality

$$\frac{a}{b} = 1 + \frac{a-b}{b} \leq \exp\left(\left|\frac{a-b}{b}\right|\right),$$

we get

$$\begin{aligned} \frac{g(\tau^k(x))}{g(\tau^k(y))} &= \frac{\frac{1}{g(\tau^k(y))}}{\frac{1}{g(\tau^k(x))}} \\ &\leq \exp\left(\left|\frac{1}{g(\tau^k(x))} - \frac{1}{g(\tau^k(y))}\right|\right) \\ &\leq \exp(M \cdot d_{n-k}), \end{aligned}$$

and thus,

$$\frac{g_n(x)}{g_n(y)} \leq \exp\left(M \cdot \sum_{k=0}^{n-1} d_{n-k}\right) \leq \exp(M \cdot D).$$

We have established condition (1) with

$$d = \exp(M \cdot D).$$

We now invoke the harmonic average of slopes condition to prove condition (2): let $\varepsilon = \frac{1}{2}\delta$ and $r = s_H < 1$. (It is important to note that we did not use the lengths of the first and last intervals of the partition to define δ .) It is enough to notice that, for any $J' \in \mathcal{P}^{(n)}$, $\tau^n(J')$ is an interval and if $\lambda(\tau^n(J')) < \varepsilon$, then $\tau^n(J')$ can intersect at most two intervals of \mathcal{P} . Thus, $\sum_{J' \in \mathcal{P}(\tau^n(J'))} \sup g \leq s_H = r < 1$.

Condition (3) is satisfied by definition. This completes the proof. \square

4. Stability of ACIM for families of maps

The main motivation for this investigation is to prove stability of the acim for maps with turning fixed or periodic points. The general setting is as follows. Let τ_0 be a map with an invariant density f_0 and $\{\tau_\gamma\}_{\gamma>0}$ a family of maps with invariant

densities f_γ such that τ_γ converge to τ_0 in some sense as γ converges to 0. Question: under what conditions does $f_\gamma \rightarrow f_0$ in some sense? Such problems were investigated in many articles but usually using the bounded variation technique [1,4].

Theorem 3. Let the family $\{\tau_\gamma\}_{\gamma>0} \subset \mathcal{T}_\Sigma$ satisfies the assumptions of Rychlik's Theorem in a uniform way, i.e. with the same constants and $\tau_\gamma \rightarrow \tau_0$ almost uniformly as $\gamma \rightarrow 0$. If τ_0 has exactly one acim, then $f_\gamma \rightarrow f_0$ in L^1 as $\gamma \rightarrow 0$. In the general case every limit point of the family $\{f_\gamma\}$, as $\gamma \rightarrow 0$, is an invariant density of τ_0 .

Proof. The proof follows from Theorem 11.2.3 of [3] which we recall below with appropriate changes. \square

Theorem 4. Let $\tau_\gamma \in \mathcal{T}$, $\gamma \geq 0$. Let the invariant densities of $\{f_\gamma\}_{\gamma \geq 0}$ be uniformly bounded in L^∞ . If $\tau_\gamma \rightarrow \tau_0$ almost uniformly as $\gamma \rightarrow 0$, then any limit point of $\{f_\gamma\}_{\gamma>0}$, as $\gamma \rightarrow 0$, is a τ_0 -invariant density. If $\{\tau_0, f \cdot m\}$ is ergodic, then $f_\gamma \rightarrow f_0$ in L^1 .

We now describe two families of maps for which Theorem 3 applies.

Example 1. Let $\tau_0 \in \mathcal{T}_\Sigma$ satisfy the harmonic average condition $s_H < 1$. Let τ_γ be defined on the same partition $\mathcal{P} = \{I_1, I_2, \dots, I_q\}$ and $\tau_\gamma \rightarrow \tau_0$, as $\gamma \rightarrow 0$, in $C^1(\text{int}(I_i))$ for all $i = 1, 2, \dots, q$. We also assume that the summable oscillation condition is satisfied uniformly for $\{\tau_\gamma\}_{\gamma \geq 0}$. Then, the family $\{\tau_\gamma\}_{\gamma \geq 0}$ satisfies the assumptions of Theorem 3.

Example 2. Let $\tau_0 \in \mathcal{T}_\Sigma$ satisfy the harmonic average condition $s_H < 1$. Let each τ_γ be piecewise expanding on the partition $\mathcal{P}_\gamma = \{I_0^{(\gamma)}, I_2^{(\gamma)}, \dots, I_{q+1}^{(\gamma)}, I_i^{(\gamma)} = [a_{i-1}^{(\gamma)}, a_i^{(\gamma)}], i = 0, 1, 2, \dots, q+1\}$. We allow the possibility that $I_0^{(\gamma)}$ or $I_{q+1}^{(\gamma)}$ or both of them are empty. We assume $a_i^{(\gamma)} \rightarrow a_i^{(0)}$ as $\gamma \rightarrow 0$, $i = 0, 1, 2, \dots, q$. Then, automatically $a_{-1}^{(\gamma)} \rightarrow a_{-1}^{(0)}$ and $a_{q+1}^{(\gamma)} \rightarrow a_{q+1}^{(0)}$ as $\gamma \rightarrow 0$. We also assume that the summable oscillation condition and the harmonic average condition are satisfied uniformly for $\{\tau_\gamma\}_{\gamma \geq 0}$. If $\tau_\gamma \rightarrow \tau_0$ almost uniformly as $\gamma \rightarrow 0$, then the family $\{\tau_\gamma\}_{\gamma \geq 0}$ satisfies the assumptions of Theorem 3.

Stability of acim was obtained in [13] under additional much stronger conditions on the family of transformations. The two main stronger conditions assumed in [13] are the following.

- (i) There exists a constant $\delta > 0$ such that for any τ_γ in the family of maps there exists a finite partition \mathcal{K}_γ such that for any $J \in \mathcal{K}_\gamma$, $\tau_{\gamma|J}$ is one-to-one, $\tau_\gamma(J)$ is an interval, and

$$\min_{J \in \mathcal{K}_\gamma} \text{diam}(J) > \delta.$$

- (ii) For any $m \geq 1$, there exists $\delta_m > 0$ such that if

$$\mathcal{K}_\gamma^{(m)} = \bigvee_{j=0}^{m-1} \tau_\gamma^{-j}(\mathcal{K}_\gamma)$$

then

$$\min_{J \in \mathcal{K}_\gamma^{(m)}} \text{diam}(J_m) \geq \delta_m > 0.$$

From these conditions it follows that the family of densities is weakly compact in L^1 .

5. Examples

The results of this paper allow us to answer a question posed in [5].

Example 3. Let τ_γ , $0 \leq \gamma < \varepsilon_0 < 1/2$, be a map defined by

$$\tau_\gamma(t) = \begin{cases} \frac{1}{2} - \gamma + (1 + 2\gamma)t, & 0 \leq t < \frac{1}{2}; \\ 2 - 2t, & \frac{1}{2} \leq t \leq 1. \end{cases} \quad (5)$$

τ_0 is exact with invariant density $f_0 = \frac{2}{3}\chi_{[0,1/2]} + \frac{4}{3}\chi_{[1/2,1]}$. Is this acim stable under perturbation given by the family $\{\tau_\gamma\}_{\gamma>0}$? τ_0 has a turning point $1/2$ which is periodic with period 3. Previously known methods did not give an answer to this question.

We will consider the family of third iterates $\{\tau_\gamma^3\}_{\gamma>0}$. τ_0^3 is shown in Fig. 1(a) and a typical τ_γ^3 is shown in Fig. 1(b). The slopes of τ_γ^3 are $s_1 = s_3 = s_7 = 2 + 8\gamma + 8\gamma^2$, $s_2 = s_4 = s_6 = 4 + 8\gamma$, and $s_5 = 8$. Since τ_0 is exact, τ_0^3 is also exact with the same acim and stability of acim for τ_0^3 implies the same for τ_0 . We can see that the family $\{\tau_\gamma^3\}_{\gamma>0}$ satisfies the conditions of Example 2. Thus, τ_0 has a stable acim.

Fig. 1. The 3rd iterates of maps of Example 3.

Example 4. Let us consider the following W-shaped map:

$$\tau_0(t) = \begin{cases} 1 - 6t, & 0 \leq t < \frac{1}{6}; \\ -\frac{2}{9} + \frac{5}{3}t - \frac{\sqrt{6}}{81}(3 - 9t)^{3/2}, & \frac{1}{6} \leq t \leq \frac{1}{3}; \\ -3t + \frac{4}{3}, & \frac{1}{3} \leq t < \frac{4}{9}; \\ \frac{9}{5}t - \frac{4}{5}, & \frac{4}{9} \leq t \leq 1. \end{cases} \quad (6)$$

The derivative of the second branch is

$$\tau'_{0,2}(t) = \frac{5}{3} + \frac{\sqrt{6}}{2} \left(\frac{1}{3} - t \right)^{1/2}.$$

The minimal moduli of the slopes are $s_1 = 6$, $s_2 = \frac{5}{3}$, $s_3 = 3$ and $s_4 = \frac{9}{5}$ and we have

$$s_H = \max \left\{ \frac{1}{6} + \frac{3}{5}, \frac{3}{5} + \frac{1}{3}, \frac{1}{3} + \frac{5}{9} \right\} = \max \left\{ \frac{23}{30}, \frac{14}{15}, \frac{24}{27} \right\} = \frac{24}{27} < 1.$$

The map τ is not C^{1+1} because the derivative of τ_2 is not Lipschitz. Thus, no previous result can prove the stability of acim for map τ . On the right hand side of Fig. 2 we present an untypical perturbation of τ . We define it as follows

$$\tau_\gamma(t) = \begin{cases} 1 - \frac{6}{1+6\gamma}t, & 0 \leq t < \frac{1}{6} + \gamma; \\ -\frac{2}{9} + \frac{5}{3}t - \frac{\sqrt{6}}{81}(3 - 9t)^{3/2} + A(\gamma)t + B(\gamma), & \frac{1}{6} + \gamma \leq t \leq \frac{1}{3}; \\ -\frac{3+18\gamma}{1-9\gamma}(t - 4/9 + \gamma), & \frac{1}{3} \leq t < \frac{4}{9} - \gamma; \\ \frac{1}{2\gamma}(t - 4/9 + \gamma), & \frac{4}{9} - \gamma \leq t < \frac{4}{9} + \gamma, \\ \frac{9}{5-9\gamma}(t - 4/9 - \gamma), & \frac{4}{9} + \gamma \leq t \leq 1, \end{cases} \quad (7)$$

where $A(\gamma), B(\gamma)$ are constants such that $\tau_{\gamma,2}(1/3) = 1/3 + 2\gamma$ and $\lim_{\gamma \rightarrow 0} A(\gamma) = \lim_{\gamma \rightarrow 0} B(\gamma) = 0$. It is easy to check that for γ small enough the family $\{\tau_\gamma\}$ satisfies uniformly the assumptions of Rychlik's Theorem and that τ_γ converges almost uniformly to τ_0 . Thus, the acims of the τ_γ s converge to the acim of τ_0 .

Fig. 2. Example of W -map not in class C^{1+1} and its untypical perturbation.
